

HEAT

The word "HEAT" is rendered in a bold, black, blocky font. Each letter is outlined with a thick, bright yellow border. The top edges of the letters are jagged and irregular, resembling flames or a fire effect. The background is a soft-focus image of a sunset or sunrise, with a large, bright yellow sun in the upper center and a sky transitioning from light yellow to a pale pinkish-purple. The lower portion of the image shows a layer of white, fluffy clouds.

# ENERGY

- **Definition:** Energy is the ability to do work.

- **Examples:**

- Light
- Sound
- Mechanical energy
- Heat
- Electricity
- Nuclear energy
- Chemical energy

**Types:**

**Kinetic**

**Potential**

# TYPES OF ENERGY

- Kinetic energy is the energy of motion.
- Potential energy is stored energy.
  - atomic energy - energy stored in the nucleus of an atom [ $E = mc^2$ ]
  - chemical energy - energy stored in chemical bonds
- Heat is kinetic energy. What is moving?

**Heat is the energy of moving molecules.**

- When something heats up, the molecules move faster.

# TEMPERATURE vs. HEAT

- Are heat and temperature the same?
- Imagine a glass of water and a pail of water each absorb the same amount of heat.
- Which has the higher temperature? (or are they the same?)

## WHY?

# AN ANALOGY

**You win the lottery and convert it to \$1 bills.**

## Scenario 1

- You win \$1,000,000.
- You stand in the center of a room of 1,000 people and toss the bills in the air.
- There is a mad scramble for the money.

How much do people get? **\$1,000**

## Scenario 2

- You win \$100,000.
- You stand in the center of a room of 20 people and toss the bills in the air.
- There is a mad scramble for the money.

How much do people get? **\$5,000**

- **Heat and temperature work like money.**
- **No matter how much heat you have, the more molecules that share it, the lower the average.**

# DEFINITIONS

- **Heat** is the total kinetic energy of moving molecules.
- **Temperature** is the average kinetic energy of moving molecules.
- Which has more heat, a cup of water at  $99^{\circ}\text{C}$  or the Atlantic Ocean at  $10^{\circ}\text{C}$ ?

The total is higher here.

The average is higher here.

# THE RELATIONSHIP

- As heat is added to a substance, the temperature increases.
  - Heat and temperature are directly proportional.
- As the mass of the substance being heated increases, the temperature change becomes smaller.
  - Mass and temperature are indirectly proportional.
- This relationship can be expressed mathematically.

# THE EQUATION

- Heat is proportional to the product of the mass and the temperature change.
- The equation is not an equality.
  - joules  $\neq$  g  $\times$   $^{\circ}\text{C}$  (It can't be equal! Look at the units!!)
- How can we get an equality? (We need one to do calculations!)

$$q \propto m \times \Delta T$$

$q$  = heat (joules)

$m$  = mass (g)

$\Delta T$  = temperature change  
(K *or*  $^{\circ}\text{C}$ )

$\propto$  = proportional to

# THE EQUALITY PROBLEM

- On December 1, 2007, a 3.3 lb white truffle was sold at auction for \$330,000.
- This means a 1lb chunk of the fungus would fetch \$100,000. Still, since the units are different, . . .
  - 1 lb  $\neq$  \$100,000,
  - and 3.3 lb  $\neq$  \$330,000,
  - but they are proportional.
- The price per pound,  $\frac{\$100,000}{1 \text{ lb}}$ , is a constant that turns this proportionality into an equality.

$$\$330,000 = 3.3 \text{ lb} \times \frac{\$100,000}{1 \text{ lb}}$$

$$\$100,000 = 1 \text{ lb} \times \frac{\$100,000}{1 \text{ lb}}$$

# SPECIFIC HEAT CAPACITY

- **Specific heat** is the amount of heat needed to raise the temperature of 1 gram of a substance by 1°C.
- Specific heat is the constant that turns the relationship  $q \propto m \times \Delta T$  into an equality.
- Many heat problems are based on water. The specific heat of water is  $4.2 \text{ J/g}^\circ\text{C}$ .

$$q = m \times C \times \Delta T$$

$q$  = heat (joules)

$m$  = mass (g)

$\Delta T$  = temperature change  
(K or °C)

$C$  = specific heat capacity  
(J/g°C)

# SAMPLE PROBLEM 1

How much heat is needed to raise the temperature of 500. g of water by 15°C?

- **Step1:** List the known variables

- $m = 500. \text{ g}$
- $C = 4.2 \text{ J/g}^\circ\text{C}$
- $\Delta T = 15^\circ\text{C}$

- **Step 2:** Determine the product

- $q = mC\Delta T$
- $q = (500. \cancel{\text{g}})(4.2 \cancel{\text{ J/g}^\circ\text{C}})(15 \cancel{^\circ\text{C}})$
- $q = 31,500 \text{ J} \approx 32,000 \text{ J}$

# SAMPLE PROBLEM 2

## How much heat is needed to raise the temperature of 25 g of water from 27°C to 47°C?

(In this problem, the initial temperature [ $T_i$ ] and the final temperature [ $T_f$ ] are given instead of the temperature change [ $\Delta T$ ].)

- **Step 1:** Determine  $\Delta T$  ( $\Delta T = T_f - T_i$ )
  - $\Delta T = 47^\circ\text{C} - 27^\circ\text{C} = 20.^\circ\text{C}$
- **Step 2:** List the known variables
  - $m = 25 \text{ g}$
  - $C = 4.2 \text{ J/g}^\circ\text{C}$
  - $\Delta T = 20.^\circ\text{C}$
- **Step 3:** Determine the product
  - $q = mC\Delta T$
  - $q = (25 \text{ g})(4.2 \text{ J/g}^\circ\text{C})(20^\circ\text{C})$
  - $q = 2100 \text{ J}$

# SAMPLE PROBLEM 3

**What is the final temperature when 84 joules of heat are added to 2.0 gram of water at 15°C?**

(In this problem, the amount of heat  $[q]$  and the initial temperature  $[T_i]$  are given. The final temperature  $[T_f]$  and the temperature change  $[\Delta T]$  are the unknowns.)

- **Step 1:** List the known variables
  - $q = 84 \text{ J}$
  - $m = 2.0 \text{ g}$
  - $C = 4.2 \text{ J/g}^\circ\text{C}$
  - $T_i = 15^\circ\text{C}$
- **Step 2:** Determine  $\Delta T$  ( $q = mC\Delta T$ )
  - $84 \text{ J} = (2.0 \text{ g})(4.2 \text{ J/g}^\circ\text{C})(\Delta T)$
  - $\Delta T = 10^\circ\text{C}$
- **Step 3:** Determine  $T_f$  ( $\Delta T = T_f - T_i$ )
  - $10^\circ\text{C} = T_f - 15^\circ\text{C}$
  - $T_f = 25^\circ\text{C}$

# OTHER SPECIFIC HEATS

- Consider two frying pans, one with a metal handle, and the other with a wood handle:
- Which one is more comfortable to handle with the bare hands after it has been on a hot flame? **The wood handle**
- Why are they different?
- Wood has a higher specific heat than metal. Wood is more resistant to temperature change. The wood is cooler even though it absorbed as much heat as the metal.
- It is possible to do calculations with specific heats other than that of water ( $4.2 \text{ J/g}^\circ\text{C}$ ). It is also possible for specific heat to be the unknown.

# SAMPLE PROBLEM 4

The specific heat of gold is  $0.134 \text{ J/g}^\circ\text{C}$ . How many joules will it take to make the temperature of a 20.0 g nugget go up  $10.0^\circ\text{C}$ ?

(In this problem, the specific heat of gold is used instead of the specific heat of water.)

- **Step 1:** List the known variables

- $m = 20.0 \text{ g}$
- $C = 0.134 \text{ J/g}^\circ\text{C}$
- $T_i = 10^\circ\text{C}$

- **Step 2:** Determine the product

- $q = mC\Delta T$
- $q = (20.0 \text{ g})(0.134 \text{ J/g}^\circ\text{C})(10^\circ\text{C})$
- $q = 26.8 \text{ J}$

# SAMPLE PROBLEM 5

**What is the specific heat of silicon if a 5.00 g sample is heated from 22.0°C to 42.0°C by adding 75.24 J?**

(In this problem, the specific heat is the unknown.)

- **Step 1:** Determine  $\Delta T$  ( $\Delta T = T_f - T_i$ )
  - $\Delta T = 42.0^\circ\text{C} - 22.0^\circ\text{C} = 20.0^\circ\text{C}$
- **Step 2:** List the known variables
  - $q = 75.24 \text{ J}$
  - $m = 5.00 \text{ g}$
  - $\Delta T = 20.0^\circ\text{C}$
- **Step 3:** Solve for the specific heat,  $C$  ( $q = mC\Delta T$ )
  - $75.24 \text{ J} = (5.00 \text{ g})(C)(20.0^\circ\text{C})$
  - $C = 0.752 \text{ J/g}^\circ\text{C}$
